Module 5: Statistical inference (II)

Siyue Yang

05/21/2022

Outline

This module we will review

- Basics of parametric inference
- Methods for generating parametric estimators
- Maximum likelihood estimators
- Delta method
- Optimization method for finding MLE in R (Newton-Raphson, EM algorithm)

Parametric inference

Definition (Parametric models)

$$\mathfrak{F} = \{ f(\mathbf{x}; \theta) : \theta \in \Theta \}$$

where the $\Theta \subset \mathbb{R}^k$ is the parameter space and $\theta = (\theta_1, \dots, \theta_k)$ is the parameter.

Goal of parametric inference

ullet estimate the parametric heta (assume we known the form of the density).

Parameter of interest and nuisance parameter

Often, we are interested in estimating some function $T(\theta)$.

For example, if $X \sim N(\mu, \sigma^2)$, then

- Parameters: $\theta = (\mu, \sigma)$
- Parameter space: $\Theta = \{(\mu, \sigma) : \mu \in \mathbb{R}, \sigma > 0\}$

If the goal is to estimate the μ then

- Parameter of interest: $T(\theta) = \mu$
- ullet Nuisance parameter: σ

Methods for generating parametric estimators

- Method of moments
- Maximum likelihood

Method of moments

Suppose that the parameter $\theta = (\theta_1, \dots, \theta_k)$ has k components.

• For $1 \le j \le k$, define the j^{th} moment

$$\alpha_j \equiv \alpha_j(\theta) = \mathbb{E}_{\theta}\left(X^j\right) = \int x^j dF_{\theta}(x)$$

• The j^{th} sample moment

$$\widehat{\alpha}_j = \frac{1}{n} \sum_{i=1}^n X_i^j$$

• The method of moments estimator $\widehat{\theta}_n$

$$\alpha_{1}\left(\widehat{\theta}_{n}\right) = \widehat{\alpha}_{1}$$

$$\vdots$$

$$\alpha_{k}\left(\widehat{\theta}_{n}\right) = \widehat{\alpha}_{k}$$

Maximum likelihood

- Parametric model: $f(x; \theta), X_1, \dots, X_n$ iid
- Likelihood function

$$\mathcal{L}_n(\theta) = \prod_{i=1}^n f(X_i; \theta)$$

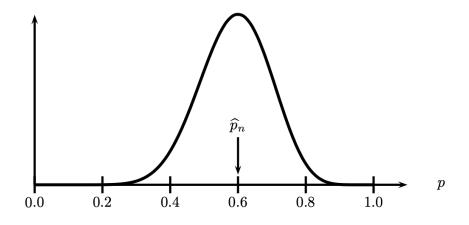

• The log-likelihood function

$$\ell_n(\theta) = \log \mathcal{L}_n(\theta) = \sum_{i=1}^n \log f(X_i; \theta)$$

• The maximum likelihood estimator (MLE)

$$\hat{ heta}_{ extit{MLE}} = rg\max_{ heta} \mathcal{L}(heta)$$

An example of MLE

Likelihood function for Bernoulli with n=20 and $\sum_{i=1}^{n} X_i = 12$. The MLE is $\hat{\rho}_n = 12/20 = 0.6$.

Why is maximum likelihood estimation so popular?

- A unified framework for estimation.
- Under mild regularity conditions, MLEs are
 - **① consistent** \rightarrow converge to the true value in probability as $n \rightarrow \infty$, i.e.

$$\lim_{n\to\infty} P(|\hat{\theta} - \theta| \le \epsilon) = 1 \quad \forall \epsilon > 0$$

- **2** asymptotically normal $\rightarrow \sqrt{n}(\hat{\theta} \theta) \sim N(0, \sigma^2)$ for large n
- **3** asymptotically efficient \rightarrow achieve the lowest variance for large n
- **4 equivariant** \rightarrow if $\hat{\theta}$ is the MLE for θ then $g(\hat{\theta})$ is the MLE for $g(\theta)$

Steps to find the MLE

Write out the likelihood

$$\mathcal{L}(\theta) = f(X_1, \ldots, X_n; \theta)$$

Simplify the log likelihood

$$\ell(\theta) = \log \mathcal{L}(\theta)$$

- **3** Take the derivative of $\ell(\theta)$ with respect to the parameter of interest, θ Set =0
- **9** Solve for θ (get $\hat{\theta}_{MLE}$)
- $\textbf{ § Check that } \hat{\theta}_{MLE} \text{ is a maximum } \left(\tfrac{\partial^2}{\partial \theta^2} \ell(\theta) < 0 \right)$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(p) = \prod_{i=1}^n f(X_i; p) = \prod_{i=1}^n p^{X_i} (1-p)^{1-X_i} = p^{S} (1-p)^{n-S}$$

where $S = \sum_i X_i$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(p) = \prod_{i=1}^n f(X_i; p) = \prod_{i=1}^n p^{X_i} (1-p)^{1-X_i} = p^{S} (1-p)^{n-S}$$

where $S = \sum_i X_i$

2. Log-likelihood

$$\ell_n(p) = S \log p + (n - S) \log(1 - p)$$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(p) = \prod_{i=1}^n f(X_i; p) = \prod_{i=1}^n p^{X_i} (1-p)^{1-X_i} = p^{S} (1-p)^{n-S}$$

where $S = \sum_i X_i$

2. Log-likelihood

$$\ell_n(p) = S \log p + (n - S) \log(1 - p)$$

3. MLE (Solved the scoring equation)

$$\ell_n'(p) = 0$$

The MLE is $\hat{p}_n = S/n$.

Score function and Fisher information

Score function

$$s(X; \theta) = \frac{\partial \log f(X; \theta)}{\partial \theta}$$

Fisher information

$$I_n(\theta) = \mathbb{V}_{\theta} \left(\sum_{i=1}^n s(X_i; \theta) \right)$$
$$= \sum_{i=1}^n \mathbb{V}_{\theta} (s(X_i; \theta))$$

Asymptotic normality

Let $se = \sqrt{\mathbb{V}\left(\widehat{\theta}_n\right)}$. Under appropriate regularity conditions, the following hold:

• se $\approx \sqrt{1/I_n(\theta)}$ and

$$\frac{\left(\widehat{\theta}_n - \theta\right)}{\mathsf{se}} \rightsquigarrow \mathit{N}(0,1).$$

2 Let $\widehat{\operatorname{se}} = \sqrt{1/I_n\left(\widehat{\theta}_n\right)}$. Then,

$$\frac{\left(\widehat{\theta}_n - \theta\right)}{\widehat{\text{se}}} \rightsquigarrow N(0, 1)$$

Let

$$C_n = (\widehat{\theta}_n - z_{\alpha/2}\widehat{se}, \widehat{\theta}_n + z_{\alpha/2}\widehat{se})$$

Then, \mathbb{P}_{θ} ($\theta \in C_n$) $\to 1 - \alpha$ as $n \to \infty$.

Elements of likelihood estimation

One random variable: Given a model for X which assumes X has a density $f(x; \theta)$, $\theta \in \Theta \subset \mathbb{R}^k$, we have the following definitions:

likelihood function	$L(\theta; x) = c(x)f(x; \theta)$
log-likelihood function	$\ell(\theta; x) = \log L(\theta; x)$
score function	$u(\theta) = \partial \ell(\theta; x) / \partial \theta$
observed information function	$j(\theta) = -\partial^2 \ell(\theta; x) / \partial \theta \partial \theta^T$
expected information (in one observation)	$i(\theta) = \mathrm{E}_{\theta} \left\{ U(\theta) U(\theta)^T \right\}$

Elements of likelihood estimation (i.i.d.)

Independent observations: When we have X_i independent, identically distributed from $f(x_i; \theta)$, then, denoting the observed sample $\mathbf{x} = (x_1, \dots, x_n)$ we have:

likelihood function $L(\theta; \mathbf{x}) = \prod_{i=1}^n f\left(x_i; \theta\right)$ log-likelihood function $\ell(\theta) = \ell(\theta; \mathbf{x}) = \sum_{i=1}^n \ell\left(\theta; x_i\right)$ maximum likelihood estimate $\hat{\theta} = \hat{\theta}(\mathbf{x}) = \arg\sup_{\theta} \ell(\theta)$ score function $U(\theta) = \ell'(\theta) = \sum U_i(\theta)$ observed information function $j(\theta) = -\ell''(\theta) = -\ell''(\theta; \mathbf{x})$ observed (Fisher) information $j(\hat{\theta}) = \mathbb{E}_{\theta} \left\{ U(\theta)U(\theta)^T \right\} = ni_1(\theta)$

Delta method

If au=g(heta) where g is differentiable and g'(heta)
eq 0 then

$$\frac{(\widehat{\tau}_n - \tau)}{\widehat{\mathsf{se}}(\widehat{\tau})} \rightsquigarrow \textit{N}(0,1)$$

where $\widehat{ au}_n = g\left(\widehat{\theta}_n\right)$ and

$$\widehat{\operatorname{se}}(\widehat{\tau}_n) = \left| g'(\widehat{\theta}) \right| \widehat{\operatorname{se}}(\widehat{\theta}_n)$$

Hence, if

$$C_{n} = \left(\widehat{\tau}_{n} - z_{\alpha/2}\widehat{se}\left(\widehat{\tau}_{n}\right), \widehat{\tau}_{n} + z_{\alpha/2}\widehat{se}\left(\widehat{\tau}_{n}\right)\right)$$

then $\mathbb{P}_{\theta} (\tau \in C_n) \to 1 - \alpha$ as $n \to \infty$.

Let $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

Let $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

The MLE of ψ is $\widehat{\psi} = \log \widehat{p}/(1-\widehat{p})$. Since, g'(p) = 1/(p(1-p)), according to the delta method

$$\widehat{\operatorname{se}}\left(\widehat{\psi}_{n}\right)=\left|g'\left(\widehat{p}_{n}\right)\right|\widehat{\operatorname{se}}\left(\widehat{p}_{n}\right)=\frac{1}{\sqrt{n\widehat{p}_{n}\left(1-\widehat{p}_{n}\right)}}$$

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

The MLE of ψ is $\widehat{\psi} = \log \widehat{p}/(1-\widehat{p})$. Since, g'(p) = 1/(p(1-p)), according to the delta method

$$\widehat{\operatorname{se}}\left(\widehat{\psi}_{n}\right)=\left|g'\left(\widehat{p}_{n}\right)\right|\widehat{\operatorname{se}}\left(\widehat{p}_{n}\right)=\frac{1}{\sqrt{n\widehat{p}_{n}\left(1-\widehat{p}_{n}\right)}}$$

An approximate 95 percent confidence interval is

$$\widehat{\psi}_n \pm \frac{2}{\sqrt{n\widehat{p}_n(1-\widehat{p}_n)}}$$

MLE in R

Sometimes, there is no closed-form solution, so we need to use optimization methods to find the maximum of the log-likelihood.

- optim() find values of some parameters that minimizes some function.
- Newton-Raphson
- EM-algorithm

Newton-Raphson

Derivative of the log-likelihood around θ^3 :

$$0 = \ell'(\widehat{\theta}) \approx \ell'\left(\theta^{j}\right) + \left(\widehat{\theta} - \theta^{j}\right)\ell''\left(\theta^{j}\right)$$

Solving for $\widehat{\theta}$ gives

$$\widehat{ heta} pprox heta^j - rac{\ell'\left(heta^j
ight)}{\ell''\left(heta^j
ight)}.$$

This suggests the following iterative scheme:

$$\widehat{ heta}^{j+1} = heta^j - rac{\ell'\left(heta^j
ight)}{\ell''\left(heta^j
ight)}$$

In the multiparameter case, the mle $\hat{\theta}=\left(\hat{\theta}_1,\ldots,\hat{\theta}_k\right)$ is a vector and the method becomes

$$\widehat{\theta}^{j+1} = \theta^j - H^{-1}\ell'\left(\theta^j\right)$$

where $\ell'(\theta^j)$ is the vector of first derivatives and H is the matrix of second derivatives of the log-likelihood.

Expectation-Maximization (EM) algorithm

Idea: Iterate between taking an expectation then maximizing.

Suppose we have data Y whose density $f(y;\theta)$ leads to a log-likelihood that is hard to maximize. However we can find another variable Z s.t. $f(y;\theta) = \int f(y,z;\theta)dz$ and $f(y,z;\theta)$ is easy to maximize.

- Pick a starting value θ^0 . Now for $j=1,2,\ldots$, repeat steps E and M below:
- (The E-step): Calculate

$$J\left(\theta\mid\theta^{j}\right)=\mathbb{E}_{\theta^{j}}\left(\log\frac{f\left(Y^{n},Z^{n};\theta\right)}{f\left(Y^{n},Z^{n};\theta^{j}\right)}\mid Y^{n}=y^{n}\right).$$

The expectation is over the missing data Z^n treating θ^i and the observed data Y^n as fixed.

• (M-step) Find θ^{j+1} to maximize $J(\theta \mid \theta^j)$
