Module 5: Statistical inference (II)

Yaqi Shi

July 17, 2024

Outline

This module we will review

- Basics of parametric inference
- Methods for generating parametric estimators
- Maximum likelihood estimators
- Delta method
- Optimization method for finding MLE in R (Newton-Raphson, EM algorithm)

Parametric inference

Definition (Parametric models)

$$\mathfrak{F} = \{ f(x; \theta) : \theta \in \Theta \}$$

where the $\Theta \subset \mathbb{R}^k$ is the parameter space and $\theta = (\theta_1, \dots, \theta_k)$ is the parameter.

Goal of parametric inference

ullet estimate the parametric heta (assume we known the form of the density).

Parameter of interest and nuisance parameter

Often, we are interested in estimating some function $T(\theta)$.

For example, if $X \sim N(\mu, \sigma^2)$, then

- Parameters: $\theta = (\mu, \sigma)$
- Parameter space: $\Theta = \{(\mu, \sigma) : \mu \in \mathbb{R}, \sigma > 0\}$

If the goal is to estimate the μ then

- Parameter of interest: $T(\theta) = \mu$
- Nuisance parameter: σ

Methods for generating parametric estimators

- Method of moments
- Maximum likelihood

Method of moments

Definitions

- $\mathbb{E}(X^k)$ is the k^{th} (theoretical) moment of the distribution, for k=1,2,...
- $M_k = \frac{1}{n} \sum_{i=1}^n X_i^k$ is the k^{th} sample moment, for k = 1, 2, ...

Steps to find MoM

The basic idea behind this form of the method is to:

- Equate the first sample moment about the origin M₁ = ½ ∑_{i=1}ⁿ X_i = X̄ to the first theoretical moment E(X).
 Equate the second sample moment about the origin M₂ = ½ ∑_{i=1}ⁿ X_i²
- Equate the second sample moment about the origin $M_2 = \frac{1}{n} \sum_{i=1}^{n} X_i^2$ to the second theoretical moment $\mathbb{E}(X^2)$.
- Continue equating sample moments bout the origin until you have as many equations as you have parameters.
- Solve for the parameters

Example of MoM (Bernoulli)

Let $X_1, ..., X_n$ be Bernoulli random variables with parameter p. What is the method of moments estimator of p?

Example of MoM (Bernoulli)

Let $X_1, ..., X_n$ be Bernoulli random variables with parameter p. What is the method of moments estimator of p?

Only one parameter p, so we only need to equate the first moment.

$$\mathbb{E}(X_i) = p = M_1 = \frac{1}{n} \sum_{i=1}^n X_i = \bar{X}.$$

So,

$$\hat{p}_{MoM} = \bar{X}$$

Example of MoM (Normal)

Let $X_1,...,X_n$ be normal random variables with mean μ and variance σ^2 . What are the method of moments estimators of the mean μ and variance σ^2 ?

Example of MoM (Normal)

Let $X_1,...,X_n$ be normal random variables with mean μ and variance σ^2 . What are the method of moments estimators of the mean μ and variance σ^2 ?

Two parameters, so we need to equate the first and the second moment.

$$E(X_i) = \mu = M_1, E(X_i^2) = \sigma^2 + \mu^2 = M_2.$$

So,

$$\hat{\mu}_{MoM} = \bar{X}, \hat{\sigma}_{MoM}^2 = \frac{1}{n} \sum_{i=1}^n X_i^2 - \bar{X}^2.$$

Asymptotic properties

Under mild regularity conditions, MoM estimators are

• Consistent \to converge to the true value in probability as $n \to \infty$, i.e.

$$\lim_{n\to\infty} P(|\hat{\theta} - \theta| \le \epsilon) = 1 \quad \forall \epsilon > 0$$

- Asymptotically Normal $\rightarrow \sqrt{n}(\hat{\theta} \theta) \sim N(0, \sigma^2)$ for large n
- However, they are usually NOT Asymptotically Efficient

Maximum likelihood

- Parametric model: $f(x; \theta), X_1, \dots, X_n$ iid
- Likelihood function

$$\mathcal{L}_n(\theta) = \prod_{i=1}^n f(X_i; \theta)$$

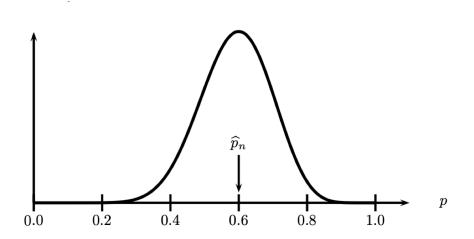

The log-likelihood function

$$\ell_n(\theta) = \log \mathcal{L}_n(\theta) = \sum_{i=1}^n \log f(X_i; \theta)$$

• The maximum likelihood estimator (MLE)

$$\hat{ heta}_{ extit{MLE}} = rg\max_{ heta} \mathcal{L}(heta)$$

An example of MLE

Likelihood function for Bernoulli with n=20 and $\sum_{i=1}^{n} X_i = 12$. The MLE is $\hat{p}_n = 12/20 = 0.6$.

Steps to find the MLE

Write out the likelihood

$$\mathcal{L}(\theta) = f(X_1, \dots, X_n; \theta)$$

Simplify the log likelihood

$$\ell(\theta) = \log \mathcal{L}(\theta)$$

- **3** Take the derivative of $\ell(\theta)$ with respect to the parameter of interest, θ Set =0
- **9** Solve for θ (get $\hat{\theta}_{MLE}$)
- **⑤** Check that $\hat{\theta}_{MLE}$ is a maximum $\left(\frac{\partial^2}{\partial \theta^2}\ell(\theta) < 0\right)$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(\rho) = \prod_{i=1}^n f(X_i; \rho) = \prod_{i=1}^n \rho^{X_i} (1-\rho)^{1-X_i} = \rho^{S} (1-\rho)^{n-S}$$

where $S = \sum_i X_i$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(p) = \prod_{i=1}^n f(X_i; p) = \prod_{i=1}^n p^{X_i} (1-p)^{1-X_i} = p^{S} (1-p)^{n-S}$$

where $S = \sum_{i} X_{i}$

2. Log-likelihood

$$\ell_n(p) = S \log p + (n - S) \log(1 - p)$$

Suppose we have an iid sample $\{X_1, \ldots, X_n\}$ with $X_i \sim \text{Bernoulli}(p)$. Find the MLE for p.

1. The likelihood

$$\mathcal{L}_n(p) = \prod_{i=1}^n f(X_i; p) = \prod_{i=1}^n p^{X_i} (1-p)^{1-X_i} = p^{S} (1-p)^{n-S}$$

where $S = \sum_i X_i$

2. Log-likelihood

$$\ell_n(p) = S \log p + (n - S) \log(1 - p)$$

3. MLE

$$\ell_n'(p) = 0$$

The MLE is $\hat{p}_n = S/n$.

Asymptotics of MLE

Under mild regularity conditions, MLEs are

• Consistent o converge to the true value in probability as $n o \infty$, i.e.

$$\lim_{n\to\infty} P(|\hat{\theta}-\theta| \le \epsilon) = 1 \quad \forall \epsilon > 0$$

- Asymptotically normal $\rightarrow \sqrt{n}(\hat{\theta} \theta) \sim N(0, \sigma^2)$ for large n
- Asymptotically efficient
- equivariant o if $\hat{\theta}$ is the MLE for θ then $g(\hat{\theta})$ is the MLE for $g(\theta)$

Asymptotic Efficiency

Cramér-Rao bound

The variance of any *unbiased* estimator $\hat{\theta}$ of θ is bounded by the reciprocal of the Fisher information $I(\theta)$:

$$\operatorname{Var}(\hat{\theta}) \geq \frac{1}{I(\theta)},$$

where
$$I(\theta) = n\mathbb{E}\left[\left(\frac{\partial \ell}{\partial \theta}\right)^2\right]$$
.

Both MoM estimators are asymptotically unbiased, but MLE estimators achieves the CR lower bound.

MLE in R

Sometimes, there is no closed-form solution, so we need to use optimization methods to find the maximum of the log-likelihood.

- optim() find values of some parameters that minimizes some function.
- Newton-Raphson
- EM-algorithm

Example using optim()

```
set.seed(42) # For reproducibility
sample data <- rbinom(1000, size = 1, prob = 0.3) # Assuming success probability of 0.3
# Log-likelihood function for Bernoulli distribution
log likelihood bernoulli <- function(p, data) {
  n <- length(data)
  \log \text{likelihood} \leftarrow \sup (\text{data} * \log(p) + (1 - \text{data}) * \log(1 - p))
  return(-log likelihood) # Negative to be used with optimization functions (minimization)
# Initial parameter value for optimization (probability of success)
initial param <- 0.8
# Find MLE using optim
result <- optim(
  par = initial param, fn = log likelihood bernoulli,
  data = sample_data, method = "Brent", lower = 0, upper = 1
# MLE estimate of p
mle_p <- result$par
# Print the result
cat("MLE of p:", mle_p, "\n")
```

MLE of p: 0.293

Newton-Raphson

Derivative of the log-likelihood around θ :

$$0 = \ell'(\widehat{\theta}) \approx \ell'\left(\theta^{j}\right) + \left(\widehat{\theta} - \theta^{j}\right)\ell''\left(\theta^{j}\right)$$

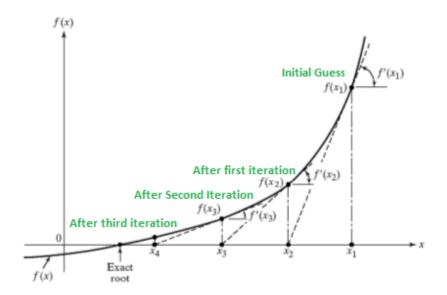

Solving for $\widehat{\theta}$ gives

$$\widehat{\theta} pprox \theta^j - rac{\ell'\left(\theta^j\right)}{\ell''\left(\theta^j\right)}.$$

This suggests the following iterative scheme:

$$\widehat{ heta}^{j+1} = heta^j - rac{\ell'\left(heta^j
ight)}{\ell''\left(heta^j
ight)}$$

Illustration

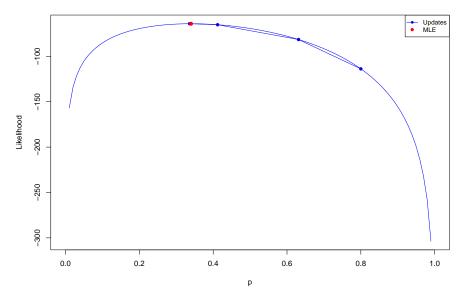

NR algorithm in R

```
# First derivative of the log-likelihood function
log_likelihood_bernoulli_prime <- function(p, data) {
  n <- length(data)
  d log likelihood <- sum(data / p - (1 - data) / (1 - p))
  return(-d log likelihood) # Negative to be used with optimization functions (minimization)
# Second derivative of the log-likelihood function
log_likelihood_bernoulli_double_prime <- function(p, data) {
  n <- length(data)
  dd_log_likelihood <- sum(-data / p^2 - (1 - data) / (1 - p)^2)
  return(-dd log likelihood) # Negative to be used with optimization functions (minimization)
}
# Initial parameter value for optimization (probability of success)
initial param <- 0.8
# Newton-Raphson algorithm for optimization
tolerance <- 1e-8
max iterations <- 1000
p <- initial_param
for (i in 1:max_iterations) {
  p new <- p - log likelihood bernoulli prime(p, sample data) /
    log_likelihood_bernoulli_double_prime(p, sample_data)
  if (abs(p_new - p) < tolerance) {
    break
  p <- p_new
# Print the result
cat("MLE of p:", p, "\n")
```

MLE of p: 0.293

Solution Trajectory

Expectation-Maximization (EM) algorithm

- We will introduce the expectation-maximization (EM) algorithm in the context of Gaussian mixture models.
- Let $N(\mu, \sigma^2)$ denote the probability distribution function for a normal random variable.
- In this scenario, we have that the conditional distribution $X_i|Z_i=k\sim N(\mu_k,\sigma_k^2)$

Likelihood Function

The marginal distribution of each X_i is

$$P(X_i = x) = \sum_{k=1}^{K} P(Z_i = k) P(X_i = x | Z_i = k) = \sum_{k=1}^{K} \pi_k N(x; \mu_k, \sigma_k^2)$$

Given the data is independent, the likelihood is

$$L(\theta|X_1,\ldots,X_n) = \prod *i = 1^n * \sum k = 1^K \pi_k N(x;\mu_k,\sigma_k^2)$$

and the log-likelihood is

$$\ell(\theta) = \sum_{i=1}^{n} \log \left[\sum_{k=1}^{K} \pi_k N(x; \mu_k, \sigma_k^2) \right]$$

where $\theta = \{\mu_1, ..., \mu_k, \sigma_1, ..., \sigma_k, \pi_1, ..., \pi_k\}.$

Complete Likelihood

The complete likelihood takes the form

$$P(X,Z \mid \mu,\sigma,\pi) = \prod_{i=1}^{n} \prod_{k=1}^{K} \pi_{k}^{I(Z_{i}=k)} N(x_{i} \mid \mu_{k},\sigma_{k})^{I(Z_{i}=k)}$$

so the complete log-likelihood takes the form:

$$\log(P(X,Z\mid\mu,\sigma,\pi)) = \sum_{i=1}^{n} \sum_{k=1}^{K} I(Z_i = k) \left(\log(\pi_k) + \log(N(x_i\mid\mu_k,\sigma_k))\right)$$

E-step

In practice, we do not observe the latent variables, so we consider the expectation of the complete log-likelihood with respect to the posterior of the latent variables. The expected value of the complete log-likelihood is therefore:

$$\begin{split} &E_{Z|X}[\log(P(X,Z\mid\mu,\sigma,\pi))]\\ &= E_{Z|X}\left[\sum_{i=1}^{n}\sum_{k=1}^{K}I\left(Z_{i}=k\right)\left(\log\left(\pi_{k}\right) + \log\left(N\left(x_{i}\mid\mu_{k},\sigma_{k}\right)\right)\right)\right]\\ &= \sum_{i=1}^{n}\sum_{k=1}^{K}P\left(Z_{i}=k\mid X\right)\left\{\log\left(\pi_{k}\right) + \log\left[N\left(x_{i}\mid\mu_{k},\sigma_{k}\right)\right]\right\} \end{split}$$

Note that $P(Z_i = k|X)$ is the posterior distribution of Z_i given the observations:

$$P\left(Z_{i}=k\mid X_{i}\right)=\frac{P\left(X_{i}\mid Z_{i}=k\right)P\left(Z_{i}=k\right)}{P\left(X_{i}\right)}=\frac{\pi_{k}N\left(\mu_{k},\sigma_{k}^{2}\right)}{\sum_{k=1}^{K}\pi_{k}N\left(\mu_{k},\sigma_{k}\right)}$$

M-estp

- First choose initial values for μ, σ, π so you can compute $P(Z_i = k \mid X_i)$.
- Then with $P(Z_i = k \mid X_i)$ fixed, maximize the expected complete log-likelihood above with respect to μ_k, σ_k, π_k .

Example (Mixture of Two Normal)

In this example, we will assume our mixture components are fully specified Gaussian distributions (i.e the means and variances are known), and we are interested in finding the maximum likelihood estimates of the π_k 's. Assume we have K=2 components, so that:

$$X_i \mid Z_i = 0 \sim N(5, 1.5)$$

 $X_i \mid Z_i = 1 \sim N(10, 2)$

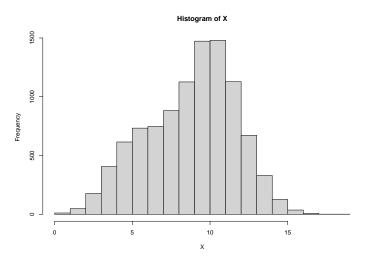

The true mixture proportions will be $P(Z_i = 0) = 0.25$ and $P(Z_i = 1) = 0.75$. First we simulate data from this mixture model

EM in R

```
# mixture components
mu.true \leftarrow c(5, 10)
sigma.true \leftarrow c(1.5, 2)
# determine Z_i
Z \leftarrow rbinom(500, 1, 0.75)
# sample from mixture model
X \leftarrow rnorm(10000,
  mean = mu.true[Z + 1],
  sd = sigma.true[Z + 1]
```

EM in R

hist(X, breaks = 15)

EM in R

```
log_likelihood_mixture <- function(theta, data) {</pre>
  mu1 <- theta[1]
  mu2 \leftarrow theta[2]
  sigma1 <- theta[3]
  sigma2 <- theta[4]
  pi <- theta[5]</pre>
  n <- length(data)
  log likelihood <- sum(</pre>
    log(pi * dnorm(data, mean = mu1, sd = sigma1) +
      (1 - pi) * dnorm(data, mean = mu2, sd = sigma2))
  return(log_likelihood)
```

```
# E-step: Compute the component proportions for each data point
e_step <- function(data, mu1, mu2, sigma1, sigma2, pi) {
  p1 <- pi * dnorm(data, mean = mu1, sd = sigma1)
  p2 <- (1 - pi) * dnorm(data, mean = mu2, sd = sigma2)
  # Compute the proportions for each data point
  proportions <- p1 / (p1 + p2)
  return(proportions)
# M-step: Update the parameters (means, variances, and mixture proportion)
m_step <- function(data, proportions) {</pre>
  pi <- mean(proportions)
  mu1 <- sum(proportions * data) / sum(proportions)
  mu2 <- sum((1 - proportions) * data) / sum(1 - proportions)
  sigma1 <- sqrt(sum(proportions * (data - mu1)^2) / sum(proportions))
  sigma2 <- sqrt(sum((1 - proportions) * (data - mu2)^2) / sum(1 - proportions))
  return(c(mu1, mu2, sigma1, sigma2, pi))
```

```
# EM algorithm to estimate means and variances
em_algorithm <- function(data, max iterations = 1000, tolerance = 1e-8, initial params = NULL) {
 # Initial quesses for the parameters
 if (is.null(initial_params)) {
    initial params <- c(mean(data), mean(data), sd(data), sd(data), 0.5)
 params <- initial_params
 log_likelihood_prev <- -Inf
 for (i in 1:max_iterations) {
    # E-step: Compute the component proportions
   proportions <- e_step(data, params[1], params[2], params[3], params[4], params[5])
    # M-step: Update the parameters
   new_params <- m_step(data, proportions)</pre>
    # Compute the log-likelihood to check for convergence
   log likelihood <- log likelihood mixture(new params, data)
    # Check for convergence
   if (abs(log likelihood - log likelihood prev) < tolerance) {
      cat("Total Number of Iterations: ", i, "\n")
      break
    # Update parameters and log-likelihood
    params <- new_params
    log_likelihood_prev <- log_likelihood
 return(params)
```

```
# Run the EM algorithm on the generated data
estimated params <- em algorithm(X)
## Total Number of Iterations: 2
# Print the estimated parameters
cat("Estimated mean 1:", estimated_params[1], "\n")
## Estimated mean 1: 8.7721
cat("Estimated mean 2:", estimated_params[2], "\n")
## Estimated mean 2: 8.7721
cat("Estimated variance 1:", estimated_params[3]^2, "\n")
## Estimated variance 1: 8.199793
cat("Estimated variance 2:", estimated_params[4]^2, "\n")
## Estimated variance 2: 8 199793
cat("Estimated mixture proportion:", estimated_params[5], "\n")
```

Estimated mixture proportion: 0.5

What happened?

- There is no guarantee that the EM algorithm converges to a global maximum of the likelihood.
- To address this issue, one approach is to try different initial parameter values and run the EM algorithm multiple times.

```
# Run the EM algorithm with random initial parameter
estimated params <- em algorithm(X,
 initial params = c(runif(2, min(X), max(X)),
                   runif(2, 0, max(X) - min(X)),
                    runif(1, 0, 1))
## Total Number of Iterations: 383
# Print the estimated parameters
cat("Estimated mean 1:", estimated params[1], "\n")

```

Delta method

Theorem (The Delta Method).

Suppose that

$$\frac{\sqrt{n}\left(Y_{n}-\mu\right)}{\sigma}\rightsquigarrow N(0,1)$$

and that g is a differentiable function such that $g'(\mu) \neq 0$. Then

$$\frac{\sqrt{n}\left(g\left(Y_{n}\right)-g(\mu)\right)}{\left|g'(\mu)\right|\sigma}\rightsquigarrow N(0,1).$$

In other words,

$$Y_n pprox \mathcal{N}\left(\mu, rac{\sigma^2}{n}
ight) \quad ext{ implies that } \quad g\left(Y_n
ight) pprox \mathcal{N}\left(g(\mu), \left(g'(\mu)
ight)^2 rac{\sigma^2}{n}
ight).$$

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

Let $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

Let $X_1, \ldots, X_n \sim \text{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

The MLE of ψ is $\widehat{\psi} = \log \widehat{p}/(1-\widehat{p})$. Since, g'(p) = 1/(p(1-p)), according to the delta method

$$\widehat{\operatorname{se}}\left(\widehat{\psi}_{n}\right) = \left|g'\left(\widehat{p}_{n}\right)\right| \widehat{\operatorname{se}}\left(\widehat{p}_{n}\right) = \frac{1}{\sqrt{n\widehat{p}_{n}\left(1-\widehat{p}_{n}\right)}}$$

Let $X_1, \ldots, X_n \sim \mathsf{Bernoulli}(p)$ and let $\psi = g(p) = \log(p/(1-p))$.

The Fisher information function is I(p) = 1/(p(1-p))

The estimated standard error of the MLE \hat{p}_n is

$$\widehat{\mathrm{se}} = \sqrt{\frac{\widehat{p}_n \left(1 - \widehat{p}_n\right)}{n}}$$

The MLE of ψ is $\widehat{\psi} = \log \widehat{p}/(1-\widehat{p})$. Since, g'(p) = 1/(p(1-p)), according to the delta method

$$\widehat{\operatorname{se}}\left(\widehat{\psi}_{n}\right)=\left|g'\left(\widehat{p}_{n}\right)\right|\widehat{\operatorname{se}}\left(\widehat{p}_{n}\right)=\frac{1}{\sqrt{n\widehat{p}_{n}\left(1-\widehat{p}_{n}\right)}}$$

An approximate 95 percent confidence interval is

$$\widehat{\psi}_n \pm \frac{2}{\sqrt{n\widehat{p}_n(1-\widehat{p}_n)}}$$
